

Soil degradation

“Soil management is sustainable if the supporting, provisioning, regulating, and cultural services provided by soil are maintained or enhanced without significantly impairing either the soil functions that enable those services or biodiversity. The balance between the supporting and provisioning services for plant production and the regulating services the soil provides for water quality and availability and for atmospheric greenhouse gas composition is a particular concern” (GSP, 2017).

Contingency plan

Prevention

- Effects of forwarding on soil hydrological properties in thinning operation in northern Spain

- The aim of this study was to evaluate the effects of forwarding on the hydrological properties of a high compaction-risk soil with a moisture content of almost 62%.
- A single-factor factorial design with three replications was used involving three traffic intensities of a Dingo AD6-24 forwarder (3, 6 and 9 passes).
- Four undisturbed soil samples were taken in each treatment plot and specific soil properties were measured in the laboratory: bulk density, porosity, saturated hydraulic conductivity and gravimetric water content -10 kPa (field capacity).

Contingency plan

Prevention

- Effects of forwarding on soil hydrological properties in thinning operation in northern Spain
- The results demonstrated that 3 passes of the forest machine are enough to significantly increase bulk density with successive passes having no additional effect.
- However, additional passes (6 or 9) significantly reduced the saturated hydraulic conductivity of soils, increasing soil erosion risk.
- These results indicate that in a soil with a high compaction risk, forwarding alters its physical properties and recovery from the disturbance should be followed up.

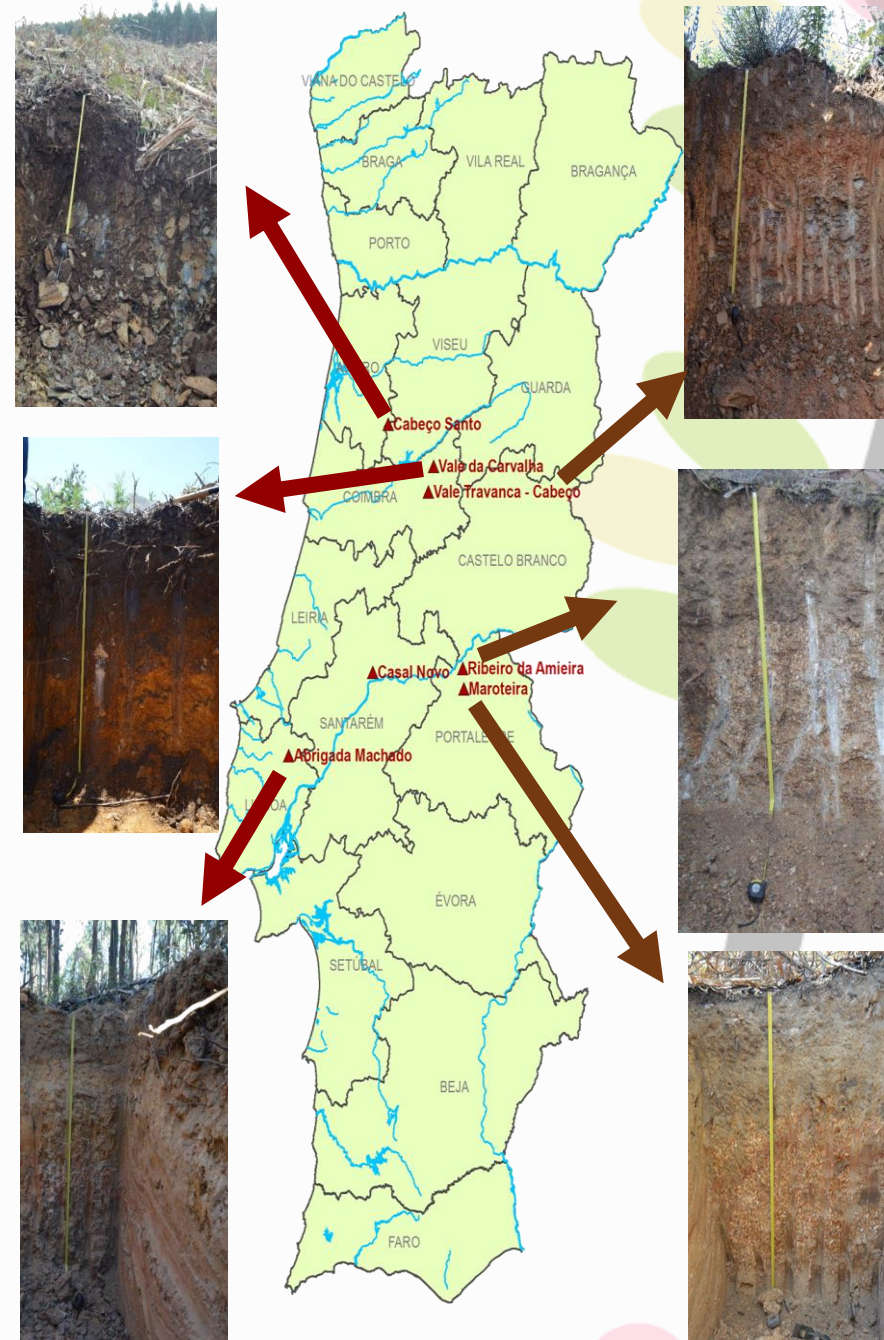

Contingency plan

Surveillance and Monitoring

- System for soil quality monitoring in Forest Plantations.
- Establish soil reference sites representative from biogeoclimatic conditions.
- Indicators for soil conditioning at reference values and after different silvicultural treatments.

Contingency plan

Crisis Management/eradication/control

Gestión de la crisis /respuesta/erradicación/control

Medidas de la primera fase

Estudiar el impacto del evento catastrófico, detectar responsabilidades, habilitar ayudas para la rehabilitación y decidir cuáles y donde se aplicarán las medidas de restauración para evitar que la degradación del suelo sea continua.

Los órganos competentes en la gestión forestal y en la vigilancia serán los responsables de activar la mesa de crisis que decidirá las medidas oportunas.

Medidas de la segunda fase

Se evaluará la efectividad de las medidas aplicadas y si se demuestra que no han sido efectivas se estudiará el por qué y se propondrán unas nuevas medidas.

Contingency plan

Rehabilitation

- Effectiveness of different treatments for post-fire soil losses reduction.

Soil erosion is a major consequences of forest fires in the North of the Iberian Peninsula.

This guide summarizes the results in terms of soil erosion reduction of different treatments carried out in Galicia (NW Spain).

Contingency plan

Rehabilitation

- Connectivity index in the planning for post-fire erosion reduction

The selection of the areas to be treated is a key step in the soil stabilization protocol after fire.

One of the most important aspects for that selection is the level of soil burn severity in the affected area.

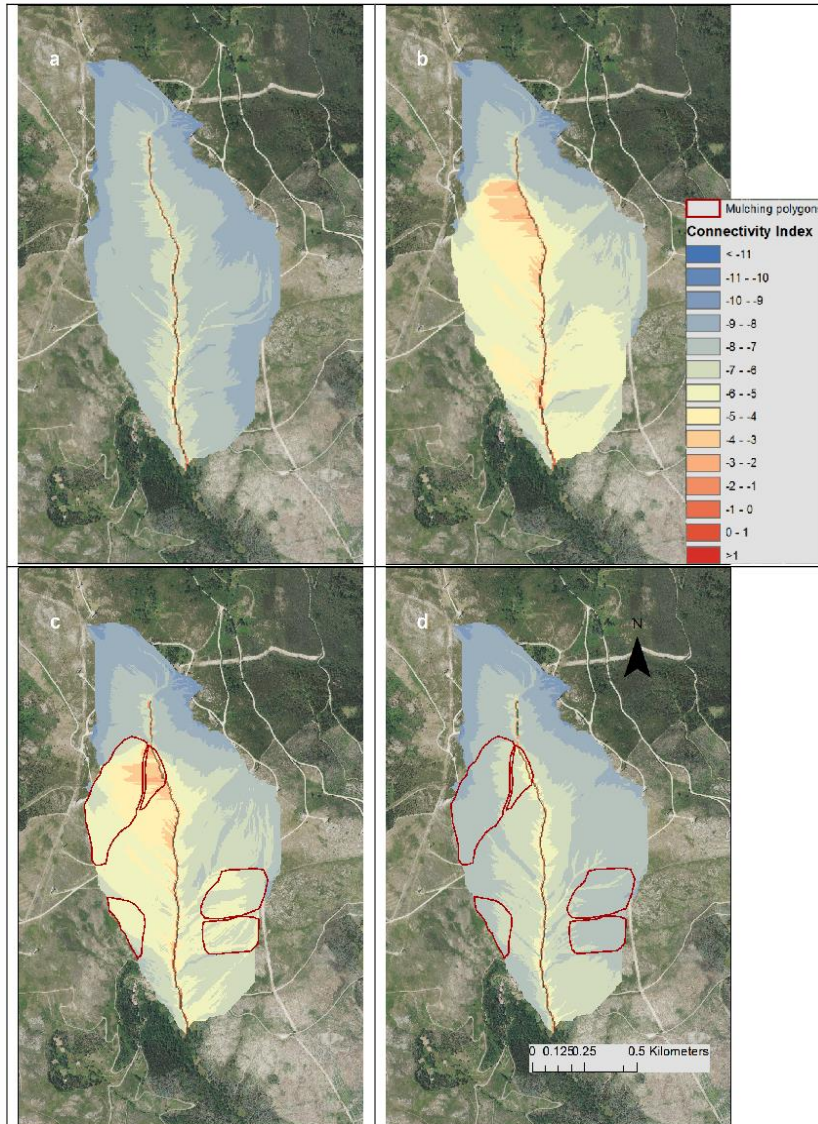

The computation of a connectivity index in catchment burned in 2016 helps to prioritize the areas to be treated. It is also possible to see how mulch application reduces catchment connectivity.

Contingency plan

Rehabilitation

Connectivity index
computed following
Borselli et al. (2008)

The modification of Borselli's connectivity index based on soil burn severity improves the original formulation and it is related with sediment delivery

Vegetation diversity

ABSTRACT

Forest mastication is frequently used as a fuel reduction treatment aimed at minimising severe wildfires in fire prone areas worldwide. In recent years, mastication of non-commercial burned trees has become common practice in NW Spain, as a way of providing cover on the burned soil and preventing erosion. However, little is known about the possible effects on soil conservation and vegetation recovery. In this study, 20 experimental plots were established in a *Pinus sylvestris* L. plantation affected by a crown fire that caused moderate-high soil burn severity in the summer of 2016. Immediately after the fire, burned trees were masticated in half of the plots, while burned trees were left standing in the other half of the plots during the first two years after the fire. The objectives of the study were to determine how mastication affected soil erosion, soil physical properties (soil penetration resistance, soil shear strength, soil bulk density) and vegetation recovery. The masticated material covered 43% of the burned soil. During the first year after wildfire + mastication, precipitation was lower than the annual mean level in the area, and the mean soil loss in the untreated burned soils (5.7 Mg ha^{-1}) was not significantly different from that in the masticated plots (5.0 Mg ha^{-1}). Mastication did not have any detrimental effects on either the soil physical properties analysed or on the regeneration of natural vegetation. The results indicated that in addition to mastication of severely burned non-commercial trees, extra mulch should be applied to reduce the risk of soil erosion. Mastication after wildfire is not detrimental to soil conservation. No advantage was obtained by leaving the standing burned trees on site, in relation to reducing soil erosion or enhancing vegetation recovery.
